### **Convex-Concave Procedure**

Stephen Boyd Max Schaller Daniel Cederberg

March 6, 2025

### Overview

### the convex-concave procedure (CCP)

- ▶ is a heuristic method for solving a specific type of nonconvex problem
- involves solving a (typically small) sequence of convex problems
- leverages expressiveness and reliability of convex optimization
- ▶ is a good street-fighting trick to know about

## Outline

Difference of convex functions

Convex-concave procedure

Example

### Difference of convex functions

**a difference of convex** (DC) function  $h: \mathbf{R}^n \to \mathbf{R}$  has the form

$$h(x) = f(x) - g(x)$$

with f and g convex

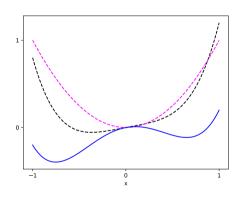

ightharpoonup any function with continuous second derivative has this form, but most useful when we have explicit expressions for f and g

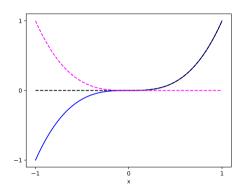

4

## Examples

$$f(x) = x^4 + 0.2x$$
,  $g(x) = x^2$ 

$$f(x) = (x^3)_+, \quad g(x) = (x^3)_-$$

f(x) in black, g(x) in magenta, h(x) = f(x) - g(x) in blue

## Quadratic function as DC

- (nonconvex) quadratic function  $h(x) = (1/2)x^T P x + q^T x + r$ ,  $P \in \mathbf{S}^n$
- ▶ decompose P into its PSD and NSD parts  $P = P_{\mathsf{psd}} P_{\mathsf{nsd}}$ ,  $P_{\mathsf{psd}}, P_{\mathsf{nsd}} \succeq 0$ 
  - $-P = Q\Lambda Q^T$  is eigenvalue decomposition
  - $P_{\mathsf{psd}} = Q \Lambda_{+} Q^{\mathsf{T}}$ , with  $\Lambda_{+} = \mathsf{max}\{0,\Lambda\}$  (elementwise)
  - $P_{\mathsf{nsd}} = Q \Lambda_{-} Q^{\mathsf{T}}$ , with  $\Lambda_{-} = \mathsf{max}\{0, -\Lambda\}$  (elementwise)
- ightharpoonup express h in DC form as h = f g with

$$f(x) = (1/2)x^T P_{psd}x + q^T x + r,$$
  $g(x) = (1/2)x^T P_{nsd}x$ 

# A simple majorizer for a DC function

ightharpoonup if (convex) g is differentiable, then for all x

$$\hat{g}(x;z) = g(z) + \nabla g(z)^T (x-z) \leq g(x)$$

(for nondifferentiable g, replace  $\nabla g(x)$  with any subgradient)

▶ for DC function h = f - g, define

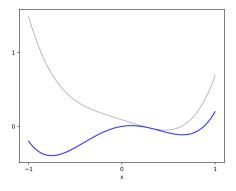

$$\hat{h}(x;z) = f(x) - \hat{g}(x;z)$$

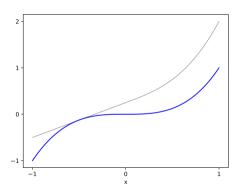

- $\hat{h}$  is convex (in x) and satisfies  $\hat{h}(x;z) \geq h(x)$  for all x,  $\hat{h}(z;z) = h(z)$
- ightharpoonup i.e.,  $\hat{h}(x;z)$  is a **majorizer** of g, tight at z

## **Examples**

$$h(x) = x^4 + 0.2x - x^2$$
,  
majorized at  $z = 0.3$ 

$$h + 0.2x - x^2$$
,  $h(x) = (x^3)_+ - (x^3)_- = x^3$ , d at  $z = 0.3$  majorized at  $z = -0.5$ 

h(x) in blue,  $\hat{h}(x;z)$  in gray

## Outline

Difference of convex functions

Convex-concave procedure

Example

# Minimizing a DC function

- (unconstrained) **DC problem**: minimize DC function h(x) = f(x) g(x)
- convex constraints can be handled as indicator functions added to f
- convex-concave procedure (CCP): iterate

$$x^{k+1} = \underset{x}{\operatorname{argmin}} \hat{h}(x; x^k) = \underset{x}{\operatorname{argmin}} (f(x) - \hat{g}(x; x^k))$$

- $\triangleright$   $x^{k+1}$  can be found via convex optimization
- CCP has no parameters, no line search / trust penalty, . . .

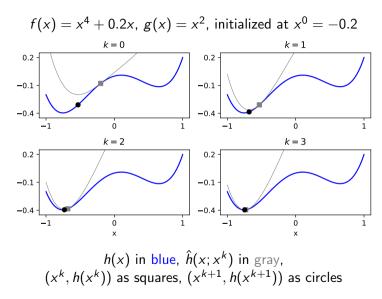

## Properties of CCP

CCP is a descent method:

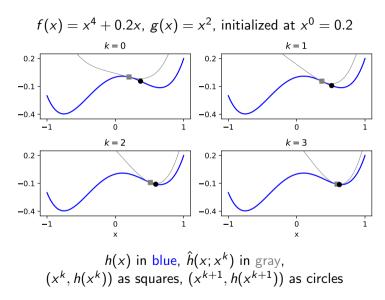

$$h(x^{k+1}) \le \hat{h}(x^{k+1}; x^k) \le \hat{h}(x^k; x^k) = h(x^k)$$

- ▶  $h(x^k)$  converges, but not necessarily to  $h^* = \inf_x h(x)$
- ▶ ultimate value  $\lim_{k\to\infty} h(x^k)$  depends on initial point  $x^0$
- standard trick: run CCP for multiple initial points; take best ultimate point found

## Example

## Example

## SAT problem

- ▶ SAT problem: find  $x_i \in \{0,1\}$  with  $Ax \leq b$
- includes 3-SAT; NP-hard
- encode Boolean constraint using  $x_i \in \{0,1\} \iff x_i^2 x_i = 0$
- ▶ SAT problem equivalent to minimizing DC function h = f g with

$$f(x) = \begin{cases} 0 & Ax \leq b, \ 0 \leq x \leq 1 \\ \infty & \text{otherwise} \end{cases} \qquad g(x) = \sum_{i=1}^{n} (x_i^2 - x_i)$$

since  $h(x) \ge 0$  for all x and

$$h(x) = 0 \iff Ax \leq b, x_i \in \{0,1\}, i = 1,\ldots,n$$

## SAT problem via CCP

ightharpoonup CCP:  $x^{k+1}$  is a solution of LP

minimize 
$$(\mathbf{1} - 2x^k)^T x$$
  
subject to  $Ax \leq b$ ,  $0 \leq x \leq \mathbf{1}$ 

**example:** find  $x \in \{0,1\}^4$  that satisfies predicate

$$(x_1 \lor x_2 \lor \neg x_3) \land (\neg x_1 \lor \neg x_2 \lor x_4) \land (\neg x_2 \lor x_3 \lor \neg x_4)$$

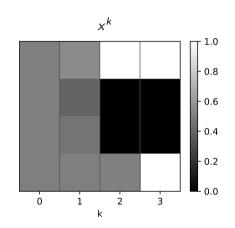

(a feasible 3-SAT instance with n = 4 variables and 3 clauses)

can be represented as

$$A = \left[ egin{array}{cccc} -1 & -1 & 1 & 0 \ 1 & 1 & 0 & -1 \ 0 & 1 & -1 & 1 \end{array} 
ight], \quad b = \left[ egin{array}{ccc} 0 \ 1 \ 1 \end{array} 
ight]$$

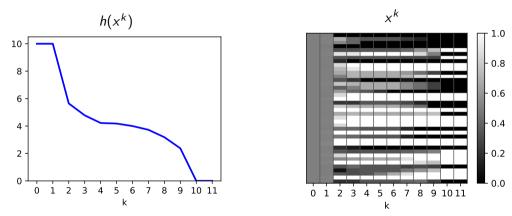

# SAT problem via CCP

```
n = 4
x = Variable(n)
xk = Parameter(n)
obj = Minimize((ones(n) - 2 * xk) @ x)
constr = [A @ x \le b, 0 \le x, x \le 1]
prob = Problem(obj, constr)
xk.value = ones(n) / 2
for _ in range(3):
    prob.solve()
    xk.value = x.value
```

# SAT problem via CCP

larger example, (feasible) 3-SAT instance with n = 40, 120 clauses

finds feasible point for 19% of random initializations

## Constrained DC problem

▶ **DC problem** with DC inequality constraints has form

minimize 
$$f_0(x) - g_0(x)$$
  
subject to  $f_i(x) - g_i(x) \le 0$ ,  $i = 1, ..., m$ 

 $f_i$  and  $g_i$  are convex

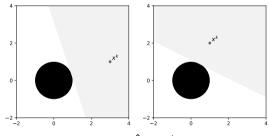

ightharpoonup CCP algorithm:  $x^{k+1}$  is solution of convex problem

minimize 
$$f_0(x) - \hat{g}_0(x; x^k)$$
  
subject to  $f_i(x) - \hat{g}_i(x; x^k) \le 0$ ,  $i = 1, ..., m$ 

- in words: linearize concave parts; solve; repeat
- ▶ if  $x^k$  is feasible, then so is  $x^{k+1}$ , and  $h(x^{k+1}) \le h(x^k)$
- CCP is a feasible descent method

### Convex restrictions

- ▶ if  $\hat{h}_i(x; x^k) = f_i(x) \hat{g}_i(x; x^k) \le 0$ , then  $h_i(x) \le \hat{h}_i(x; x^k) \le 0$
- > so convexified constraint is a **convex restriction** of original constraint
- **example**: f(x) = 0,  $g(x) = ||x||_2 1$ ,  $x^k = (3,1)$  (left) and  $x^k = (1,2)$  (right)

 $h(x) \le 0$  in white,  $\hat{h}(x; x^k) \le 0$  in gray

### Convex restrictions

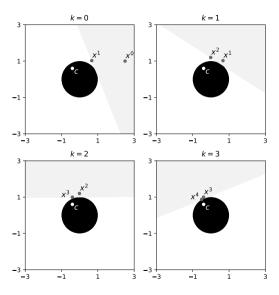

**example**: CCP for simple problem

minimize 
$$||x - c||_2$$
  
subject to  $||x||_2 \ge 1$ 

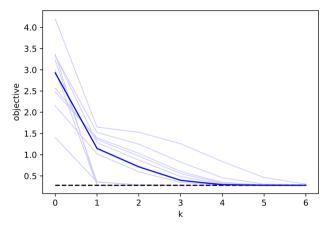

with variable  $x \in \mathbf{R}^2$ , data c with  $||c||_2 < 1$ ,  $c \neq 0$ 

- ▶ *i.e.*, find closest point to *c* that is **outside** unit ball
- ▶ solution is  $x^* = c/\|c\|_2$
- consider c = (-0.4, 0.6) and  $x^0 = (2.5, 1)$

## **CCP** iterations

## **CCP** iterations

 $\|x^k-c\|_2$  in blue,  $\|x^\star-c\|_2=1-\|c\|_2$  as dashed black line

## DC equality constraints

- ▶ linear equality constraints can just be added as indicator function to *f*
- ▶ DC equality constraints of the form  $p_i(x) = q_i(x)$ , with  $p_i$  and  $q_i$  convex, can be expressed as the pair of DC inequalities

$$p_i(x)-q_i(x)\leq 0, \qquad q_i(x)-p_i(x)\leq 0$$

## Ensuring feasibility of convex subproblems

- convex subproblems can be infeasible, even if original problem is feasible
- ▶ introduce **slack variable**  $s_i \ge 0$  for constraint i
- **penalty CCP** algorithm:  $x^{k+1}$  is solution of convex problem

minimize 
$$f_0(x) - \hat{g}_0(x; x^k) + \tau_k \sum_{i=1}^m s_i$$
  
subject to  $f_i(x) - \hat{g}_i(x; x^k) \leq s_i, \quad i = 1, \dots, m$   
 $s_i \geq 0, \quad i = 1, \dots, m$ 

where  $\tau_k > 0$  is increased between iterations

# Disciplined convex-concave programming (DCCP)

disciplined convex-concave program (DCCP) has form

minimize/maximize 
$$o(x)$$
 subject to  $l_i(x) \sim r_i(x), \quad i=1,\ldots,m,$ 

- $\triangleright$  o,  $l_i$ ,  $r_i$  are DCP convex or concave expressions
- ightharpoonup  $\sim$  can be  $\leq$ ,  $\geq$ , or =
- ightharpoonup to minimize DC objective  $f_0 g_0$ 
  - introduce epigraph variable t and DCCP constraint  $f_0(x) g_0(x) \le t$
  - minimize t
- implemented in DCCP package

# Disciplined convex-concave programming (DCCP)

### example (revisited):

```
minimize ||x - c||_2
subject to ||x||_2 \ge 1
```

with variable  $x \in \mathbf{R}^2$ , data c

```
x = Variable(2)
obj = Minimize(norm(x - c))
constr = [norm(x) >= 1]
prob = Problem(obj, constr)

x.value = [2.5, 1]
prob.solve(method='dccp')
print(x.value)
```

## Outline

Difference of convex functions

Convex-concave procedure

## Examples

# Path planning with obstacles

- $\triangleright$  find shortest path connecting points a and b in  $\mathbf{R}^d$ , avoiding m disks
- ightharpoonup disk j has center  $c_j$ , radius  $r_j$
- ightharpoonup discretize path as points  $x_0, \ldots, x_n$  and solve

minimize 
$$L$$
 subject to  $x_0=a, \quad x_n=b$  
$$\|x_i-x_{i-1}\|_2 \leq L/n, \quad i=1,\ldots,n$$
 
$$\|x_i-c_j\|_2 \geq r_j, \quad i=1,\ldots,n, \quad j=1,\ldots,m$$

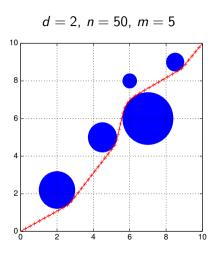

with variables L and x

useful initialization: straight line connecting a and b

## Path planning with obstacles

```
L = Variable()
x = Variable((n+1, d))
L.value, x.value = ... # initialize to straight line
constr = [x[0] == a, x[n] == b]
for i in range(1, n+1):
    constr += [norm(x[i] - x[i-1]) \le L/n]
for j in range(m):
    constr += [norm(x[i] - c[j]) >= r[j]]
prob = Problem(Minimize(L), constr)
prob.solve(method = 'dccp')
```

# Path planning with obstacles

## Floor planning

- ightharpoonup n rectangles with lower left corner  $(x_i, y_i)$ , i = 1, ..., n (variables)
- rectangle i has width  $w_i$ , height  $h_i$  (given)
- centers are  $c_i = (x_i + w_i/2, y_i + h_i/2)$
- edge set  $\mathcal{E} \subset \{1, \dots, n\}^2$  contains pairs of rectangles we want to be close
- ightharpoonup minimize  $\sum_{(i,j)\in\mathcal{E}}\|c_i-c_j\|_2^2$
- without loss of generality, we can require  $(1/n)\sum_{i=1}^{n} c_i = 0$
- these constraints and objective are convex; non-overlapping constraint is not

# Non-overlapping constraint

rectangles i and j don't overlap if

$$x_i + w_i \le x_j \quad \lor \quad x_j + w_j \le x_i \quad \lor \quad y_i + h_i \le y_j \quad \lor \quad y_j + h_j \le y_i, \quad i < j$$

i.e., rectangle i is left of, right of, below, or above rectangle j

express as inequality

$$\min \{x_i + w_i - x_j, x_j + w_j - x_i, y_i + h_i - y_j, y_j + h_j - y_i\} \le 0$$

- left-hand side is concave function of (x, y)
- ▶ so non-overlapping can be expressed as a DC inequality constraint

## Floor planning as DC problem

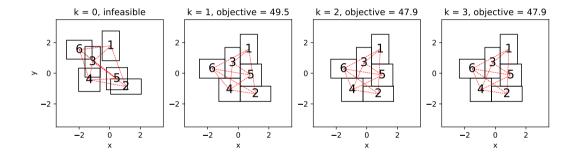

DC formulation of floor planning problem:

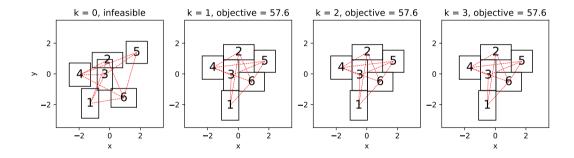

```
minimize \sum_{(i,j)\in\mathcal{E}} \|c_i - c_j\|_2^2

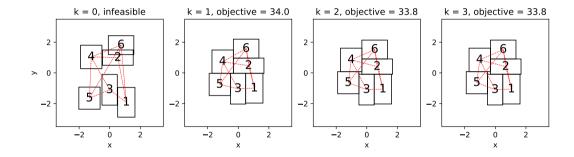

subject to \sum_{i=1}^n c_i = 0, c_i = (x_i + w_i/2, y_i + h_i/2), i = 1, \dots, n, \min\{x_i + w_i - x_j, x_j + w_j - x_i, y_i + h_i - y_j, y_j + h_j - y_i\} \le 0, i < j
```

 $\triangleright$   $x_i$ ,  $y_i$ , and  $c_i$  are variables;  $w_i$ ,  $h_i$ , and  $\mathcal{E}$  are given

n=6 rectangles; initial centers drawn uniformly from  $[-2,2]^2$ 

#### Collision avoidance

- $\triangleright$  N vehicles moving simultaneously along (discretized) time t = 0, ..., T
- vehicle i aims to travel from initial position  $x_i^{\text{init}}$  to final position  $x_i^{\text{final}}$
- ► trajectories described as

$$x_{i,t}, \quad i=1,\ldots,N, \quad t=0,\ldots,T$$

vehicles must keep minimum distance d from each other at all times

#### Collision avoidance

minimize total length of travel while avoiding collisions as

```
minimize \sum_{i=1}^{N} L_i

subject to x_{i,0} = x_i^{\text{init}}, \quad x_{i,T} = x_i^{\text{final}}, \quad i = 1, \dots, N,

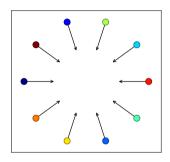

\|x_{i,t} - x_{i,t-1}\|_2 \le L_i/T, \quad i = 1, \dots, N, \quad t = 1, \dots, T,

\|x_{i,t} - x_{j,t}\|_2 \ge d, \quad i < j, \quad t = 0, \dots, T
```

- $\triangleright$   $x_{i,j}$  and  $L_i$  are variables
- $\triangleright$   $x_i^{\text{init}}$ ,  $x_i^{\text{final}}$ , and d are given

## Collision avoidance example

- N = 10 vehicles with starting points  $x_i^{\text{init}}$  uniformly on a circle around zero
- each vehicle aims to travel to opposite side of circle,  $x_i^{\text{final}} = -x_i^{\text{init}}$
- ightharpoonup minimum distance is d=1

# Collision avoidance example

# $\ell_{1/2}$ regularized regression

- ▶ minimizing  $||Ax b||_2^2 + \lambda ||x||_1$  where  $A \in \mathbf{R}^{m \times n}$  tends to yield sparse x
- (approximately) minimizing  $||Ax b||_2^2 + \lambda \sum_i |x_i|^{1/2}$  can yield sparser x
- lacktriangle sometimes called  $\ell_{1/2}$  regularization (but it's not a norm)
- not a convex problem

### DC formulation

▶ DC problem

minimize 
$$||Ax - b||_2^2 + \lambda \mathbf{1}^T t$$
  
subject to  $t \succeq 0$ ,  $|x_i| \le t_i^2$ ,  $i = 1, ..., n$ 

ightharpoonup CCP:  $x^{k+1}$  is solution of

minimize 
$$||Ax - b||_2^2 + \lambda \mathbf{1}^T t$$
  
subject to  $t \succeq 0$ ,  $|x_i| \le (t_i^k)^2 + 2t_i^k (t_i - t_i^k)$ ,  $i = 1, \ldots, n$ 

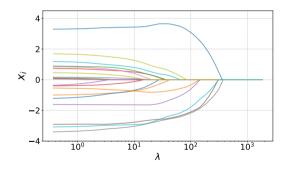

ightharpoonup so  $x^{k+1}$  is solution of weighted  $\ell_1$  regularized problem

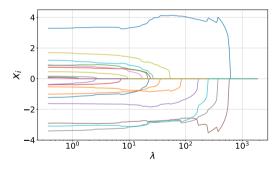

minimize 
$$||Ax - b||_2^2 + \lambda \sum_{i=1}^n \frac{1}{2t_i^k} |x_i|$$

with  $t_i^{k+1} = \frac{1}{2t_i^k} |x_i^{k+1}| + \frac{1}{2}t_i^k$  (we can impose a small minimum value for  $t_i^k$ )

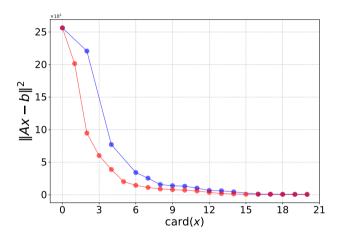

# Example

- ightharpoonup example with n = 20, m = 40
- lacktriangle regularization paths for  $\ell_1$  (left) and  $\ell_{1/2}$  (right) regularization

## Example

optimal trade off curves for  $\ell_1$  (blue) and  $\ell_{1/2}$  (red) regularization
